Introduction: The House That Listens

This volume earns one full pass, the reader is advised, and earns it exactly once: after the first reading it becomes a reference that is opened at need, not a story that is resumed. The chapters are built for that afterlife - consulted before a purchase, opened when an automation misbehaves, skimmed for their closing pages when the calendar is full. The introduction below holds the whole argument in miniature, and the chapters that follow build it clause by clause, the way the series builds every technology it takes on.

A smart home is a building whose reflexes have been upgraded. A conventional house already senses and responds - the thermostat feels a temperature, the float in a tank feels a level, the doorstop resists a swing - but it responds with one fixed reflex wired in at installation, and it forgets the response the instant it happens. The smart home changes exactly one thing: it separates the sensing from the deciding from the acting, routes all three through a layer that can remember, and therefore lets the building's behavior become a setting rather than a fact of construction. That is the entire claim. Everything sold under the label - the speakers, the bulbs, the doorbells with opinions - is an instance of that one separation, and everything that goes wrong in a smart home goes wrong at one of those three seams.

This book treats the smart home as an engineered system with a definable anatomy, because the series this volume belongs to treats every technology that way: the working parts, the load-bearing assumptions, the ways the parts fail, the money the whole thing costs, and the practice a builder can actually keep. The romantic framing - the house that anticipates you, the home that knows you better than you know yourself - is marketing shorthand for a sensing-deciding-acting loop that either runs correctly or does not, and the honest way to build one is to understand the loop, not the shorthand.

The reader should also hear the other honest claim early: a smart home is a convenience with a small set of genuine utilities attached, and the distance between the two is where most buyer regret lives. The convenience is real - lights that arrive with you, a door that reports itself, heat that follows the calendar. The utilities are narrower and more specific - energy shifted to cheap hours, an aging parent observed without interrogated, a door remembered to be locked at the hour it matters. The chapters that follow keep the two accounts separate, because the sales literature does not.

Three words do most of the work in this field, and each of them is used loosely enough to need a fence.

Sensing is the conversion of a physical condition into a signal: a presence sensor reports that something warm moved across the hallway; a power meter reports that the dryer's draw climbed; a contact sensor reports that the window's geometry changed. A sensor is wrong in characteristic ways - it fires at shadows, it misses a still occupant, it reports every microwave's cooking as an event - and a builder who has not learned a given sensor's characteristic wrongness has not yet finished installing it.

Deciding is the comparison of those signals against stored rules: if the hallway reports motion after eleven, dim the stair light to the level the household actually tolerates; if the garage door has been open longer than the household's patience setting, say so through the speaker nearest the bedroom. The deciding layer is where a smart home's character actually lives. Two houses with identical sensors and identical actuators are different buildings if one decides locally, on a hub in a closet, by rules the household wrote, and the other decides remotely, on a server the household has never seen, by rules a product team revises on Thursdays.

Acting is the conversion of a decision back into physical effect: a relay closes and the room brightens, a motor turns and the blind lowers, a valve eases and the floor warms. Actuation is the layer where the smart home touches the house's actual wiring, and it is the layer with the most failure modes per component, because it alone contains moving parts, heat, and the physics of a device that was designed to be operated by a hand and is now operated by a signal that must imitate one.

Around those three words the industry has grown a thicket of softer ones - ecosystem, intelligence, seamless, connected - and the chapters will mostly avoid the thicket. Where a chapter needs a soft concept, it will define the soft thing structurally before using it, which is the habit that keeps the whole series honest.

It is tempting to treat home automation as a consumer category - a matter of which brand of bulb to buy - and the temptation is understandable, because the packaging is the first thing a buyer meets. But the packaging is the least durable layer of the system. Products are discontinued, services are shut down, protocols are retired with an email apology, and a buyer who built on a product's name rebuilds on each cycle's grief. The durable layers are

structural: radio physics that will not change, state-machine logic that will not change, security principles that predate the industry by decades and will outlast it, and the economics of installation and maintenance that follow from the structure rather than from any vendor's catalog.

Structure is also what makes the smart home teachable. A household that has internalized the three-part anatomy can walk into any store, read any specification sheet, and place the product correctly: what does it sense, where does its decision run, what does it actuate, and which of the three seams does its price hide problems at. A household that has internalized only brand loyalty cannot, and will re-buy its understanding every three years at full price.

There is a further reason the structural treatment matters, and it is the one the series returns to in every volume: the smart home is the first engineered system most people deliberately install inside the boundary of their own privacy. A house that senses learns things about its occupants as a condition of working at all. When the door reports and the floor counts footsteps and the speaker waits for a wake word, the building is assembling a record, however fragmentary, of when people come and go, sleep and wake, and how they speak to each other over breakfast. A structural treatment refuses to treat that fact as fine print. It puts the accounting of what a home knows - and who else can read it - at the center of the design, which is where a self-respecting house would want it.

One structural fact separates the smart home from nearly every other system this series treats: it is not operated by a user. It is operated by a household - a small society of people with different tolerances, different schedules, different relationships to machinery, and different amounts of patience for a light that misfires. The engineering consequences of this fact run through every chapter, and the introduction owes them a first statement.

A household contains, at minimum, a technologist - the person reading this book, who wants the automation and will forgive its childhood - and at least one skeptic, who did not ask for the house to change and will not forgive its errors. It may contain children, who treat the system as a toy that fights back; elders, whose dignity is a design constraint the ninth chapter builds around; guests, whose consent was never asked and whose weekend the seventh chapter defends; and possibly a tenant or a landlord, whose legal relationship to the building's sensor record is a question no vendor's packaging has ever answered honestly. The smart home that treats this society as a single user with a single telephone has misunderstood its own installation, and the misunderstanding will surface as the household's politics, not as its technology: the misfire that the technologist debugs and the skeptic cites, the automation one member loves and another quietly disables, the camera one person installs and another uncovers with tape and a grudge.

The book's answer to the society problem is architectural rather than diplomatic. Modes that any member can assert, so no one negotiates with the house's inferences. Physical floors that no member can lose, so the skeptic's objections never strand them. Interfaces layered by skill, so the elder and the guest command nothing they did not already know. And rules as text, so the household's domestic policy is legible to every adult who lives under it. A smart home built this way does not merely work; it cohabits, which is the more demanding standard.

The reader deserves the negative claims with the same clarity as the positive ones, because the smart home shelf is crowded with books that are not this one.

This is not a product guide. No brand, no model, and no shopping list appears in these pages, and the reader who wants a verdict on a specific device will leave empty-handed by design: products expire on the vendor's calendar, structure survives the decade, and this book spends its pages on what survives.

This is not a hobbyist's manual of integrations. There are no step-by-step platform tutorials here, no configuration excerpts, no screenshots of dashboards, because the field's platforms churn too fast for print and their documentation is free, current, and better than any book's. What this book supplies is the knowledge that makes the documentation legible: the anatomy, the failure modes, the questions to ask of any platform whatever its name.

This is not a forecast. Where the book speaks of the decade ahead, it speaks of what the structure permits and the record predicts, in that order, and it labels its guesses as guesses. The reader who wants to know which company will win the living room has picked up the wrong instrument; the reader who wants to know the physics every eventual winner must respect - the physics of walls, the sociology of households, the mathematics of trust - is holding it.

And this is not a promise that the smart home is worth building. That verdict belongs to the household, and the ninth chapter hands over the balance sheet honestly precisely so the household can rule against it. Some houses should stay ordinary: the renter with a year left, the household whose tariff is flat and whose parents are far, the

person for whom a switch was never a burden. The book teaches the building; it does not command the building, and the reader who closes it deciding the ordinary house was the right house has used it correctly.

The chapters were built to be revisited, and three reading orders do equal justice. **The builder's order** is the printing order: chapters one through ten, each ending on its stealable page, with the introduction's definition as the spine. **The buyer's order** is for the reader standing in the aisle or the marketplace with a cart: the Definition Page, the Babel Page, the Actuation Page, and the Ledger Page first, then backward into whatever chapter the cart's questions touch. **The skeptic's order** - given to this author more than once by the most useful readers - is the eighth chapter first, the ledger of what the house will know, because the household's trust is won or lost at the accounting, and the machinery is easier to admire after the books are clean.

Whichever order wins, the ending is the same: the Audit Page of the tenth chapter, seven tests, and a household holding its own switches. The book's promise is not that the reader will love the machinery; it is that the reader will own it.

Because the chapters are kind and the subject is domestic, one warning belongs up front, stated once and then trusted to echo. A smart home is a machine installed inside a household's life, and machines inside lives fail differently than machines inside garages: their failures are witnessed by children, timed against lateness, and priced in the currency of a family's patience. The field's beginner error is not technical at all - it is building too much, too fast, with the enthusiasm of a new tool and the schedule of a hobbyist's weekend, and delivering the household a house that is impressive for a month and then quietly disabled, switch by switch, by the people it inconvenienced.

The book's antidote is its own method, and it works: one system per season, one habit per system, every fallback preserved, every rule readable. The reader who honors the incremental doctrine in the tenth chapter will not need this warning twice; the reader who skips to the buying pages should carry it through the aisles, because the most expensive smart home is not the one that failed to work - it is the one that worked correctly, on the wrong schedule, in front of a household that was never asked.

The introduction can close by issuing the reader's standing kit - the five instruments this book puts in the household's hands, named once here and built across the chapters. The **definition**, three clauses, the pocket x-ray for every product and promise. The **anatomy**, five layers, the diagnostic for every misbehavior the decade will deliver. The **doctrines** - fallback is a wire; assertion beats inference; safety rules beat everything - which settle the arguments engines and households have with each other. The **ledger**, three questions, the privacy accounting every listening house owes. And the **audit**, seven tests plus a calendar, the maintenance discipline that converts a decade of churn into errands. Five instruments, each small enough to memorize, and the reader who carries them has the whole field in pocket - which was, from the first page of the fairground's century to this one, the entire plan.

With the kit issued and the warning given, the book's own map may be read plainly: chapters one through three are the architecture - history, layers, and the wires between them; chapters four through six are the machinery - sensing, actuation, and the judgment that binds them; chapters seven through nine are the household's contract with its machinery - the interfaces, the accounting, and the payoffs; and the tenth chapter is the decade, the calendar, and the handover. Three books inside one binding, and the binding is the definition: the house that listens, deciding what to hear, who may read the record, and whose hand holds the switches - which is the only question the century ever asked, and the only one this book leaves the reader holding alone.

The chapters build from physics outward to judgment. The first chapter tells the history honestly - a century of promised houses, from the world's-fair exhibits through the laboratory homes of the computing era, and why the promise kept arriving late - and lands the definition the rest of the book uses. The second chapter dissects the responsive house into its layers, from the device at the wall to the service behind it, and shows where a decision actually runs when a room brightens.

The third chapter faces the protocol problem: a hundred small machines, from a dozen factories, on shared radio spectrum, agreeing to be understood - the physics of the spectrum, the history of the standards that fought over it, and the convergence finally underway. The fourth and fifth chapters take the two ends of the loop - what sensing actually measures and what actuation actually moves - and give each its engineering: the sensor families with their characteristic wrongnesses, the actuator families with their failure modes, and the wiring discipline that keeps both from becoming fire hazards.

The sixth chapter is the heart of the book: the rules engine, where the house's judgment lives. It builds a home

automation as a state machine, shows why naive rules race each other in the dark, and assembles the discipline that makes automations survive contact with a real household. The seventh chapter studies the interfaces - voice, application, wall panel - and their social price, because a house commanded by voice is a house with a new set of manners to learn.

The eighth chapter runs the security and privacy accounting a listening house owes its occupants, in the tradition of the classic protection literature: the threat model, the incident patterns the industry has already taught the world, and the hardening program that reduces them. The ninth chapter collects the honest payoffs - energy shifted, aging supported, accessibility delivered - and prices them without romance. The tenth chapter closes with the decade ahead, the way the series always does: the standards churn, the maintenance question nobody prices honestly, and the audit a household should run before buying anything at all.

Every chapter closes on a stealable page - one page that compresses the chapter into a checklist or table, photographable and portable into the store, the wiring closet, or the argument with the contractor. The pages are the book in miniature, and the reader in a hurry may read them first and work backward.

The series holds the same promises in every volume, and this one keeps them here where the reader can check. No vendor names: the body of this book names no company and no product, because the structure is the same under every label and the labels expire. No expiring statistics: every number in the body is either an order of magnitude, a ratio, or a value labeled as illustrative, because a book that teaches a decade's technology should survive the decade. No forecasts dressed as facts: where the book says what a technology will do, it says what the structure permits, not what a vendor promises. And no fabrication: the claims that rest on the public record sit in a citation register of durable classics at the back of the book, works chosen because they have already survived the years and can be found again long after the products discussed in any given chapter have been retired.

One promise is specific to this volume. A smart home is built inside a home, and a home is the most personal machine a person ever operates. The book will treat the household - its routines, its privacy, its aging, its budget - as a first-class engineering constraint throughout, not as a footnote to the gadgets. The best smart home is not the most automated one; it is the one whose automations the household still understands, still trusts, and still controls, in the year after the installer's invoice is forgotten.

That is the house this book builds: one that listens because the household decided it should, hears only what the household routed to it, and forgets on command. The machinery for such a house exists today, off the shelf, at prices a normal household can pay. The chapters that follow assemble it honestly, seam by seam, and leave the reader holding the switches.

Chapter 1: The House That Was Promised

Every technology arrives twice: once as an exhibit and once as an appliance. The smart home has been arriving as an exhibit for over a century, and this chapter is the history of that long first arrival, told honestly, because the gap between the exhibit and the appliance is where most of the field's disappointments were manufactured. The reader who understands why the promise kept arriving late will understand why the present decade finally delivered a usable fraction of it, and will discount the remaining gap correctly when the marketing shows it a fully choreographed kitchen.

The promised house began as a fairground attraction. Across the middle decades of the last century, the world's exhibitions and the corporate pavilions beside them staged homes of the future in which machinery performed domestic labor with theatrical timing: meals rising from hidden kitchens, floors that cleaned themselves, furniture that rearranged itself at the press of a button. The exhibits were honest in one sense and dishonest in another. They were honest that domestic labor consumed real hours and that households wanted some of those hours back. They were dishonest about the mechanism, because a fairground exhibit does not need to work for a decade without a technician; it needs to work twice an hour for a summer. The exhibit home is a stage set with electricity, and the distance between a stage set and an appliance is the entire subject of engineering.

What the exhibit era actually seeded was not technology but expectation. Several generations of fairgoers went home having seen the future of the house, and the future they saw had a fixed shape: the house would be a machine for living in, operated from a panel, responsive to commands, labor-light. When the computing industry later needed a story for why its machines should move out of the office and into the living room, the story was already sitting there, pre-built by the exhibitors. The smart home inherited its script from an age of stage sets, and parts of that script - the house that anticipates you, the panel that runs everything - are still playing, in new

packaging, today.

The first attempts to build the promise into real houses followed the script literally: push buttons. Mid-century houses of high ambition were wired with motorized everything - windows, drapes, rotating sofas - and the controls were hard panels in the walls, each button a dedicated wire to a dedicated motor. The approach died for structural reasons the modern builder should study, because they recur every time the industry forgets them.

First, a dedicated wire per function does not scale. A house with fifty controllable functions needs fifty wires to fifty switches, and the sixth renovation of the wiring is the one nobody schedules. Second, the panel had no sensing: it was a house with hands and no eyes, responsive only when somebody pressed it, which is a butler that sleeps unless poked. Third, the equipment was loud, hot, expensive, and maintenance-hungry - motors and relays of the era demanded the fairground technician the fair had, and no household had him. The push-button house delivered in small numbers, delighted visitors, and taught the industry its first honest lesson: actuation without sensing and judgment is a stage set with a mortgage.

When computing matured, the promised house gained a new patron: the research laboratory. Through the closing decades of the last century and the first of this one, laboratories in universities and corporate research parks built instrumented homes - real rooms, wired with sensors of every kind, occasionally occupied by volunteer households or by nobody at all - and used them to ask the questions the exhibits had skipped. The foundational insight of that era deserves the dignity of a citation rather than a paraphrase: the computer of the coming decades would be woven into the fabric of everyday life and, crucially, would disappear from awareness the way writing and electricity had - present everywhere, attended to nowhere. Calm technology, the era called its aspiration: the house that serves by receding.

The laboratory homes produced a body of findings that this book leans on throughout, and four of them summarize the era. First, sensing is easier than interpretation: a room full of sensors produces a river of signals, and knowing that the river means a person got up for water, not that the cat walked the hallway, is a research-grade problem the industry has been slowly industrializing ever since. Second, the household is not a user but a small society: a home is shared, its members have different tolerances for automation's errors, and an automation one member loves another member will route around. Third, routine is the raw material: homes run on repeating patterns - waking, leaving, returning, sleeping - and the patterns, not the devices, are what a smart home should be built to serve. Fourth, and least comfortable: a home that senses is a home that remembers, and the laboratory homes did their most durable work on what it means to record daily life, who should be able to read the record, and how hard that question gets when the record is of children, guests, and arguments.

Between the laboratory era and the present, the industry passed through a commercial chapter best described as a long bubble with a working core. Startups and giants shipped connected thermostats, bulbs, cameras, locks, hubs, and speakers at a pace the standards and the installers could not match. Much of the bubble's inventory is now landfill - devices orphaned when their services retired, protocols abandoned with apology emails, entire product lines discontinued in months - and the honest history records it: the field taught the public, at the public's expense, which failure modes matter most. The orphaned device, the dead cloud, the security breach, the automation that worked until the router was replaced - these are not anecdotes; they are the field's tuition, and the chapters on protocols, security, and the decade ahead treat them as first-class engineering facts.

The bubble also taught the positive lessons, and they are the reason the present moment is different. Prices fell far enough that experimentation stopped being a commitment. Radios got cheap and low-power enough that a sensor could run for years on a coin cell. The telephone became the household's universal remote control, removing an entire category of dedicated panels from the bill of materials. And the industry, burned by its own babel of incompatible radios, finally converged - late, imperfectly, but really - on a common application language for the home, a development the third chapter treats at length.

From a century of exhibits, pushes, laboratories, and bubbles, the usable definition of a smart home can now be landed, and the rest of this book builds on it clause by clause.

A smart home is a building in which the sensing, the deciding, and the acting have been pulled apart into distinct layers, linked by signals, and sent through a judgment layer that the household can read and change.

Every word of that definition does structural work. **Separated into distinct layers**: the wiring of a reflex - sensor to switch, directly - is what a conventional house already has; the smart home's entire novelty is the separation. **Connected by signals**: the layers talk over a network, which is why the third chapter exists, because the network is where a hundred machines from a dozen factories must agree on a language. **Routed through a

decision layer the household can inspect and revise**: this clause separates the smart home from the leased home, the home whose behavior is decided remotely by a product team, revised without notice, and legible to its occupants only as changes in mood. A house whose decisions the household cannot inspect is a rented reflex; a house whose decisions the household cannot revise is a landlord in the wall. The definition is not neutral about this, and neither is the book.

The definition also sets the honest scope of the subject. Nothing in it requires a house to be intelligent in the strong sense - to anticipate, to learn, to understand. Every automation this book builds is expressible as a rule over sensed conditions, and the chapters will keep the promises modest: a smart home follows stated rules over sensed conditions with actuated effects, and does so reliably, legibly, and safely. The stronger promises - the home that knows you - belong to the exhibit tradition, and the reader should enjoy them at fairs and refuse them in contracts.

Standing back, the reader deserves the structural answer to the chapter's opening question: why did the house of tomorrow take a century to arrive at all, when the vision preceded the personal computer by generations?

Because the smart home is not one technology but a stack of five, and the stack's weakest layer set the pace. Cheap, low-power radios arrived late; the party that needed them to run for a decade on nothing arrived later. The networks that knit the radios together needed standards, and standards take longer than products - the industry shipped incompatible products for twenty years waiting for the language to settle. The interfaces needed a universal device, and the telephone did not become one until the last pocket on earth carried it. The economics needed a certain threshold of disposable faith: a household will experiment at the price of a meal, not at the price of a car. And the judgment - the household's own understanding of what to automate and what to leave alone - needed a decade of public tuition in the bubble's failures to mature into the shopping sense the present market assumes.

The stack assembled. That is what changed, and it is the reason this book exists now: for the first time, all five layers are simultaneously cheap, competent, settled enough, and socially understood. The century of delay was not obstruction; it was the ordinary physics of a technology that needed four other technologies to grow up first.

The exhibit era's longest shadow is a set of questions nobody asked at the fairground door, and the modern marketplace has inherited the silence. Three questions, asked of any smart product, in any year, sort the appliance from the stage set faster than any specification table, and they deserve a section of this chapter because they are the definition's first working tool.

Who fixes it when it breaks at night? The fairground exhibit had a technician behind the curtain; the connected product has a support queue in another time zone, and the household's hallway is not a fairground - it is a load-bearing part of a life. The question decomposes into three more: does the device work manually when its intelligence fails; can the household diagnose it without the vendor's assistance; and does its failure strand anyone or merely inconvenience them. The honest product answers all three before they are asked; the exhibit-descendant answers with a firmware update scheduled for later this year.

What does it remember, and for whom? A connected device is a witness with a vendor. The exhibit kept no records; the appliance keeps them by default, and the question is not whether the house will have a memory but who owns the archive. The eighth chapter builds the full accounting; here the buyer's version suffices: the product that cannot state, on the box or in one screen of its manual, where its recordings live and how they are deleted is a product that has not finished its own design.

What happens when the maker loses interest? The exhibit closed after the summer; the product's summer lasts until the maker's roadmap says otherwise, and the graveyard of retired clouds is the field's most reliable attraction. The question is not cynical; it is arithmetic, and the structural answers - local control, shared vocabulary, exit plans - are the book's spine. The buyer who cannot say what the device becomes after its service retires has not priced the device; they have priced a subscription wearing a light fixture.

A century in, it is fair to ask what the promised house has actually delivered, and the honest scorecard is short enough to print. Delivered: the sensing layer that finally outlives its batteries; the radio families that whisper across concrete; the converged vocabulary that lets a hundred factories' devices take orders from one rules engine; and the telephone in every pocket, which quietly solved the field's oldest problem by becoming the universal panel. Delivered partially: local judgment that works but demands a systems-role the mass market never asked to play; security that is achievable but not yet default; and the aging-in-place architecture that works beautifully and sells almost not at all. Not delivered, and structurally suspicious: the house that understands you, the automation that

needs no rules, and the intelligence that replaces judgment. The scorecard is the definition's scorecard - the separation of sensing, deciding, and acting has been built; the exhibit's stronger promises remain what they always were, which is theater.

The exhibit era never ended; it moved to the internet, and the modern household's first encounter with the smart home is usually a film of one - a demonstration, staged, scored, and edited to the same grammar as the fairground's choreographed kitchens. The chapter's history earns its place in the book only if it changes how the reader watches the next demonstration, so the section teaches the watching.

A demonstration is honest about what it shows and silent about what it elides, and the elisions are the diagnostic. Watch for the hands: a demonstration whose actor touches a screen once and commands a cascade of effects is showing an interface and hiding a choreography - the cascade was a scene, rehearsed, with conditions the film does not mention (the network empty, the sensors fresh, the battery full, the room pre-mapped). Watch for the cuts: an effect that arrives via edit rather than in one continuous shot has taken the length of a firmware reboot to shoot. Watch for the house: a demonstration in an unfamiliar, immaculate space is showing a theater with a working set, and the viewer's own hallway - with its router behind the refrigerator and its toddler with a broom - is a different physics the film does not have to survive.

The structural questions transfer directly from the chapter's definition test. What sensed, what decided, where did the decision run, and what does the same scene look like at three in the morning, with the internet down, in front of the household's least patient member? A demonstration that can be re-staged honestly under those conditions is showing an appliance; the rest are showing the fair, and the reader - now holding the century's history - can see the difference in the first thirty seconds, which is precisely the competence this book promised at its cover.

One more pass over the landed definition rewards the reader, because each of its three clauses predicts a chapter of the book and a decade of the field's behavior, and predictions that come from structure are worth more than predictions that come from taste.

Separated layers predicts modularity's victory: the field's products will keep commoditizing at the layer boundaries (any bulb, any relay, any radio) while differentiating where the layers meet, and the household that buys at the boundaries - the shared vocabulary, the standard control - rides the commoditization while the household that buys the integrated marvel pays for the integration twice: once at purchase, again at every upgrade. **Signals between layers** predicts the network's sovereignty: the home's reflexes will be exactly as dependable as its whisper network, and the third chapter's physics - wall types, mesh grids, interference at dinner - will decide more household satisfaction than any feature list. **Inspectable, revisable judgment** predicts the decade's politics: the field's hardest questions - privacy, security, the estate, the vendor's right to revise a house from afar - are all questions about who holds the decision layer, and the definition is not neutral because the household is not neutral about who owns its home.

The definition, in other words, is not a summary of the chapter; it is the book's load-bearing beam, and the nine chapters that follow hang from it in order. The reader who keeps it in pocket through the retail aisle holds the century's accumulated answer to a single question - what is actually for sale here? - and the answer is always the same three clauses, whatever the packaging weighs.

A closing note on the history's use: the reader who has absorbed this chapter is now immune to the oldest trick in the field's sales literature, which is to promise the exhibit and ship the appliance. The demonstration that choreographs understanding, the roadmap slide that treats vendor intent as physics, the "next year" that arrives annually - these are the fairground's descendants, and the century of history prices them at their true worth. The appliance is worth buying; the exhibit was never for sale; and the difference - which the next chapter measures - is five layers deep and entirely open to inspection.

One final note for the decade reader: the century's history is not over, and the definition's tests will need re-running on whatever the field invents next - the gesture-controlled room, the anticipatory everything, the subscription home. The tests are ready, and they travel: what sensed, where did the decision run, who may revise it, and does the household hold the switches. The reader who keeps the four questions has the whole history of the promised house in their pocket, and every future exhibit in one glance.

A smart home is a building in which sensing, deciding, and acting are separated into layers, connected by signals, and routed through a decision layer the household can inspect and revise.

The exhibit test: if a product's demonstration requires a technician or a script, it is a stage set, not an appliance.

The separation test: ask what it senses, where the decision runs, what it actsuates - every product has three answers or it is a conventional device with a telephone attached.
The inspection test: ask where the rules live - in the house, where the household can read them, or in a remote service, where a product team reads them.
The revision test: ask who can change the behavior - the household, on any Tuesday, or only the vendor, on any Thursday.
The scope test: the honest system follows rules over sensed conditions; the systems promising understanding are selling the fairground.
