Introduction

Across the middle centuries between antiquity's end and Europe's scientific dawn, the longest continuous tradition of astronomical practice on Earth ran in Arabic. From Baghdad's ninth-century translation movement to Samarkand's fifteenth-century star catalog, the astronomers of the Islamic world observed, calculated, corrected, and extended the inherited science of the Greeks, the Persians, and the Indians; they built the instruments, compiled the tables, and named the stars that Europe would inherit; and they did it for reasons both devotional and curious, the prayer times, the qibla, the calendar, and the plain desire to know the heavens' order. This volume tells that story, the series' way: the tradition's discovery, its character, its contexts, its modern understanding, its research, its discoveries, its challenges, its future, its trivia, and its honest significance.

The story deserves the biography treatment this series gives its subjects, because Islamic astronomy is a person's-length arc: a founding, a golden age, a maturity, a transmission, and an afterlife, and the arc's stages teach the history of science's standard lessons, that knowledge moves, that patronage matters, and that a tradition's obsessions shape its achievements. The Islamic tradition's obsessions were the calendar and the mosque as much as the planets, and the result is a science whose most beautiful surviving objects are instruments, the astrolabes that sit in the world's museums as the era's emblem.

The chapters that follow keep the series' honest rule: no invented dates, no fabricated quotes, and the contested scholarship stated as contested. The reader who wants the executive summary holds it here: Islamic astronomy preserved the ancient inheritance, corrected it with better observations, built the instruments and institutions that made precision a habit, and handed Europe a working astronomy at the moment Europe was ready to use it, and the credit for that handoff is the tradition's permanent claim on the story of science.

The discovery chapter should close with the timeline's honesty, the tradition's own periods. The founding century, the translation and the first observations; the classical age, roughly the ninth through the eleventh, the great names and the standard works; the age of the regional courts, the Spanish and the Egyptian and the Central Asian schools, the tradition's widest map; the age of the institutions, Maragha and Samarkand, the observatory's built form; and the long afterlife, the teaching and the computing that continued into the modern era's dawn; the periods' names differ in the textbooks but their shape is the standard one, and the reader who holds the timeline can place every name the chapters mention.

A note on the tradition's first observatory question, the founding's standing puzzle. The chronicles report caliphal observatories, the ninth-century institutions where the first observations were organized, and the modern historians' debate, conducted carefully, concerns their form: the purpose-built institutions the later centuries would build, or the temporary observing programs the chronicles' language suggests; the discovery chapter files the puzzle because it teaches the biography's own honesty rule: the founding's buildings are less certain than its books, and the tradition's first monuments were its tables, which survive. The reader who wants certainty gets the certain part: the observations were real, the caliphs funded them, and the numbers entered the tables that Europe would inherit.

The discovery chapter's final entry is the astronomy's first dynasty of names, the founders' roll the tradition itself kept. The translators' generation, the observers of the first caliphal programs, the table-makers whose works the tradition copied, and the geometer whose name became a scientific term the modern world uses daily: the founders' roll is the discovery chapter's cast list, and the book's later chapters will give each era its due; the entry's note is the tradition's own memory, the biographical dictionaries' founders' entries, the science remembering its makers, which is the discovery's final form: a tradition that keeps its own history has discovered itself, and this volume is that self-discovery's continuation in the world's common language.

The geography sweep opens the account, because the tradition's first wonder is its map. The practice ran from the Iberian peninsula to the Central Asian cities, the observatories and the working astronomers spread across a belt of civilizations that shared a scholarly language: Baghdad and its successors, Cairo and Damascus, the Persian and Central Asian courts, the Maghrib and Andalusia; the introduction holds the breadth as the frame: this was never one nation's science but a commonwealth's, the astronomers citing one another across distances the medieval world rarely bridged, and the reader's first correction is the map itself: the tradition's history cannot be told as one city's story, the account that follows moving across the whole belt, the sky being the one subject that united the map's every corner.

The practical driver comes second in the opening, because the tradition's daily bread was timekeeping and

direction. The duties of the religious calendar: the prayer times defined by shadow lengths and twilight depths, the month's start fixed by the crescent's first sighting, the pilgrimage's direction a problem in spherical geometry; the introduction keeps the plain connection: the observatory's precision and the mosque's clock were one enterprise, the astronomers' finest mathematics answering questions the whole community asked daily, and the frame's upshot: the reader should hold the humble duties beside the grand theories, the tradition running from the crescent watch to the star catalog on one continuous line of purpose, the practical and the profound being the same tradition, the account promising both registers whole.

Chapter 1: The Discovery of Islamic Astronomy

The tradition the volume treats was uncovered in two phases: history's own scholars built it, and the moderns later reconstructed it, who have spent two centuries reconstructing what Europe's Renaissance narrative had compressed.

The founding is the eighth and ninth centuries' story, and its stages are the standard ones the historians teach. The young Abbasid state, its capital newly built on the Tigris, gathered the older world's science deliberately: the Greek texts, Ptolemy above all, translated; the Persian and Indian astronomical traditions, their tables and their methods, absorbed; and the institutional form, the caliphal library the tradition remembers as the House of Wisdom, funded to do the gathering. The first observations followed, ordered by the caliph al-Ma'mun's court to check Ptolemy's constants, and the first original tables, the zijes the tradition would produce for seven centuries, appeared within a generation. The discovery chapter's first lesson is institutional: a tradition begins when a power decides knowledge is worth funding.

The tradition's own self-discovery, its awareness of working in inheritance, is the founding's other half. The astronomers knew they were correcting Ptolemy, and they said so: the observations that disagreed with the Almagest, the tables that superseded the Greek constants, the instruments that measured better than the old world's. The tradition's characteristic tension, reverence for the inheritance and confidence in the correction, was present from the start, and the chapters that follow trace it through the tradition's whole arc.

The modern discovery, the one this series inherits, is the nineteenth and twentieth centuries' work: the manuscript hunters in the world's libraries, the editors of the surviving tables and star books, and the historians, arguing in the modern journals over the tradition's size, its originality, and its role in Europe's rise. The modern discovery's central finding, contested at its edges but solid at its core, is the tradition's reality: a thousand years of working astronomy, in Arabic first and the other Islamic languages after, spanning three continents, and leaving the modern sky its star names as the most visible relic. The discovery chapter's summary is the standard one: the tradition has been found by two audiences, its own makers and its modern historians, and each discovery remains news to the general reader, which is the volume's reason for existing.

The understanding chapter's last note is the tradition's own self-description, the words the practitioners used. The astronomer's title, the science's own name in the sources, the tradition's distinction between the star science's mathematical branch and its natural branch, the astrologer's disputed standing at the courts: the tradition's own vocabulary, now recovered in the modern editions, shows a self-aware profession with its categories, its orthodoxies, and its boundaries, and the understanding the reader should carry is that the tradition's practitioners would recognize this book's outline, their own science's story told in their own order, which is the historian's quietest compliment.

The chapter's own close returns to the five strokes' unity, with the evidence summed. The translator's confidence, proven by the corrections; the observer's discipline, proven by the tables; the mathematician's ambition, proven by the models; the believer's purposes, proven by the miqat literature's size; the builder's patience, proven by the observatories: the five strokes are the tradition's five-fingered hand, and the understanding chapter's final form is the hand's work: the tradition held the sky's science as a working grip, all fingers together, for six centuries. The reader who carries the sketch forward carries the book's own understanding, and the chapters ahead apply it.

One final stroke for the sketch, the tradition's patience with error, the craft's own honesty. The tradition's practitioners corrected themselves across generations: the tables' successive versions, the observations' refinements, the models' revisions, and the sources' own recorded doubts, the honest notes that a constant needed remeasuring; the understanding's final stroke is this patience, the tradition's assumption that the work is never finished, and the modern reader should register it as the science's own signature: the tradition's practitioners did not think they had the last word, and their tables' successive editions are the humility's monument.

The chapter's coda is the tradition's own best summary, the practitioners' five duties. The sources' own prefaces list the astronomer's obligations: to master the mathematics, to verify the observations, to serve the religious law's needs, to teach honestly, and to keep the instruments true; the understanding chapter's sketch, drawn from the modern scholarship, turns out to match the tradition's own self-portrait, stroke for stroke, and the coda's point is the book's own best evidence: the understanding the reader has formed is the understanding the tradition held, the chapters' convergence the method's quietest success. The reader carries the sketch forward with confidence, because the tradition's own words are its confirmation.

One more discovery note, the founding's first generation, the names the tradition itself remembered as founders. The astronomers of the early Abbasid courts, the translators and the first observers whose biographies the tradition's dictionaries kept, became the culture's heroes: the court astrologer-organizers, the first observatory's directors, the table-makers whose works were copied for centuries; the note matters because the tradition was self-aware from the start, keeping its own biographies, honoring its own lineages, and teaching its students the founders' stories. The discovery chapter's closing note is the tradition's own historiography, the biographical dictionaries as the science's own memory, and the modern scholar's use of them, the field's daily tool, is the founding's longest-lasting institutional product.

A final discovery note, the reader's own timeline check, the book's dating honesty stated once. The tradition's founding century, the ninth of the common era; the classical age's three centuries after; the regional courts' long middle; the institution age's thirteenth-through-fifteenth; and the afterlife's centuries to the modern dawn: the reader who holds these five periods holds the whole cast's entrances, and the book's rule, stated plainly, is the series' own: the dates given are the scholarship's standard, the contested ones are called contested, and the reader who wants the sources' precision will find them in the modern editions the bibliography of the series points to. The discovery chapter closes by keeping the biography's promise: the life story told whole, with its certainties certain and its questions open.

One last note before the chapters turn: the tradition's discovery by the reader, the volume's own purpose. The general reader's story of science, in most of the world's telling, still jumps the middle centuries, and the reader who has never met the tradition is this book's intended person; the discovery chapter's last promise is the series' own, the introduction's contract restated at the arc's start: the story told whole, the middle chapters restored, and the reader who finishes the volume a member of the tradition's modern audience, the one the medieval astronomers' patient tables were, in the longest run, computed for.

The star names' survival gets its paragraph, because the tradition's presence is visible every clear night. The bright stars of the modern sky wear the tradition's labels: the follower, the flying one, the shoulder, the navy's names carried through the Latin translations into the international catalogs, the hand lists of the observatories being transcriptions across three languages; the chapter's honest evidence: a modern observer naming the night sky reads a working Arabic vocabulary without knowing it, the survival being the tradition's most public monument, and the addition's upshot: the discovery of the tradition includes its daily unnoticed presence, the star names being the field's best recruiting poster: no other historical science remains so visible to the naked eye, the night sky being the tradition's living museum.

The collectors' trail adds a second room, because the modern reconstruction was built from surviving brass and parchment. The instruments in the world's museums: the astrolabes signed by their makers, the quadrants and the armillary spheres, the workshop traditions of the medieval cities preserved in the collections; the chapter's honest chain: the artifacts gave the moderns their anchors, the dated instruments proving the tradition's precision claims, the signed brass being as eloquent as any manuscript; and the addition's meaning: the reconstruction of the tradition was materially possible: the metal survived the centuries better than the paper, the instrument makers' names being recovered from their works, the discovery chapter crediting the artifacts as the field's founding evidence, the brass being the tradition's own testimony.

The phases of forgetting complete the chapter, because the tradition's loss and recovery have a documented shape. The European ascent: the new astronomy's triumph narrowing the old tradition's study to curiosity; the colonial era's curators: the manuscripts scattered into the European libraries, cataloged as treasure rather than read as science; the modern reversal: the twentieth century's historians reading the collections as a living scientific record, the tradition's rank restored by patient philology; the chapter's honest scale: the recovery is young, the field's real growth coming in the last two generations, and the phase's meaning: the reader holds the account's own context: this book's subject is partly the story of how history is written, the tradition's rediscovery being itself one of the tradition's modern chapters, the past being recovered by the same international methods the tradition

once practiced.
