Introduction

Space exploration is a national act. Nearly every spacecraft that has ever flown was paid for by a government, built under a public agency's name, and launched on a rocket a state chose to own. The world's space agencies, some eighty of them as of this decade, are the offices where that choice is made, and the register that follows is a tour of them: who they are, how they arose, what they can do, and what they are building next.

The register sorts honestly, because the roster itself sorts honestly. A handful of agencies can launch their own rockets to orbit. A smaller handful have carried their own astronauts. The great majority, the four score of smaller offices from South America to Southeast Asia, buy rides, build satellites, train engineers, and grow a national capability one contract at a time. The book's chapters follow that gradient deliberately, from the giants down through the middle ranks to the newest offices, because the gradient is the story: space is no longer the province of two rivals, but it is not yet the province of everyone.

The gradient's own numbers are entered here once, as the book's reference figures. The register counts roughly eighty agencies, of which about a dozen have launched, three have flown crews, and five hold the great bulk of the budget mass. The arithmetic of the gradient, plainly: capability in this trade is a steep pyramid, and the book's chapters descend it deliberately, because the register's honest view is that the pyramid's base, the utility files, is where the next decades of the story will be written, and the reader who only reads the apex will read half the register.

The register's method is the plain one used throughout this series. Each claim carries its evidence: a founding act, a launch count, a treaty, a budget line. The certain, the probable, and the argued are kept visibly separate, and the reader is invited to check every figure against its strength. Numbers are given as ranges or approximations wherever the public record is soft, and it is soft more often than a casual follower of space news would guess, because agencies publish at different levels of openness and their budgets ride exchange rates.

The commercial era has a chapter of its own, placed where it belongs. Private companies now fly most of the world's mass to orbit, and some readers will ask why a book about agencies spends its pages on government offices. The answer is in the register: the companies fly, but the agencies still write the checks, set the rules, own the deep-space programs, and hold the treaties. The register of national space offices is still the load-bearing structure of everything that reaches space, and it will remain the structure through the transitions the last chapters describe.

One register convention is entered at the door with the book's other borders. The chapters grade confidence openly: the certain, the probable, the argued, in that order, and the reader will find each grade stated where it matters. The register's founders, the trade's archivists and analysts who compiled the first such rosters in the 1960s, built the convention because the subject invites hype, and the chapters keep the convention because it works: a book that dates its claims and grades its confidence can be audited by its own readers, and an audited book earns the one thing the trade cannot buy, which is being believed next year.

The tour runs as follows. The origins first, the shock of Sputnik and the founding acts it provoked. Then the roster's tiers, then the four giant files in order of age: the Russian inheritance, the American flagship, the European consortium, and Asia's three powerhouses. Then the capability chapters, launch and human flight, the two clubs that sort the roster. Then the small and rising offices, the cooperations, the money, the law, and the coming decade. The beauty here is institutional, and it is real: a species that fought its way off the planet has built a worldwide civil service for the trip, and the civil service's register is worth reading closely.

The register's own borders are entered at the door, so the reader knows what is inside. The book covers government space offices: their founding acts, their capability, their cooperations, their money, and their law. It touches the military space programs only where the public record forces the acknowledgment, since the distinction the American act drew is thinner in practice than on paper, and it treats the commercial operators as the register's counterpart row, present wherever an agency's contract has moved a capability to the market. Everything else, the planets, the stars, the missions themselves, is the register's subject matter and other books' subject; this one is about the offices, and the offices are worth the visit.

Chapter 01: Origins

The register opens with a beep. In October 1957 the Soviet Union orbited Sputnik 1, a polished metal sphere with

four antennas, and the signal it sang to the world's radios ended an argument about who would own space. The craft itself was trivial, but the demonstration was not: a rocket built to carry warheads could place an object in orbit, and the state that did it first had made a claim the whole world heard. Within a year, the space agency as a form of government was born, twice, in reply.

The United States moved first and fastest in law. The National Aeronautics and Space Act of 1958 dissolved the old aeronautics committee, NACA, and folded its laboratories into a new civilian agency, the National Aeronautics and Space Administration, open for business that October. The act is a founding document worth reading in full, for two sentences in particular: it directs the new agency to conduct its activities so as to contribute materially to the expansion of human knowledge, and it requires that activities be devoted to peaceful purposes for the benefit of all mankind. The register's American file, the largest in the book, stands on that paper.

The Soviet Union had no such paper, and did not need one. Its space program was a military design bureau's work from the first, run by Korolev's office under state committees whose names changed with the politics, and the arrangement produced the early record: the first satellite, the first animal in orbit, the first man, the first woman, the first spacewalk, the first probe to the Moon's surface. The register keeps the honest note that the world's first space agency was not formally an agency at all, but a network of bureaus behind a state's sealed doors, and that the form emerged only decades later when the Soviet Union's inheritance was reorganized as Roscosmos.

The Soviet founding's secrecy deserves one exhibit, because the register's honest method keeps it visible. The bureau chief's name was a state secret for years after his death, the program's failures were buried, and the world's first space age ran without a public register at all. The trade's standing note, entered with the book's own purpose in view: the secrecy's cost was paid by the program itself, whose engineering culture, insulated from outside audit, bequeathed habits the modern file is still working out, and the register's comparison rows, the sealed founding against the published founding act two years later, are the book's first worked example of why the chapters insist on evidence, dates, and the open record.

Europe's founding came from embarrassment, converted into law. The countries that had produced the early rocket pioneers watched the two superpowers run away with the sky, and in the early 1960s began the committees that became ESRO, for science, and ELDO, for launchers. The launcher office failed on its own soil, and the 1975 merger of the two into the European Space Agency was Europe's second, successful attempt at a common space office, built on a principle the register notes as the consortium's signature: mandatory science subscriptions plus optional program participation, so that a small state can be a full member without buying a rocket it cannot use.

Asia's founders followed the pattern with local variations. India's INCOSPAR was established in 1962 around a sounding-rocket range, with India's space agency proper, ISRO, chartered in 1969 under a scientist-statesman, Vikram Sarabhai, whose founding doctrine, that space technology must serve the ordinary citizen before it serves prestige, still governs the file. Japan's space effort grew from university science into NASDA, the development agency of 1969. China's program began as Project 714's predecessors in the 1950s, under military discipline, and the modern civilian administrator, CNSA, was constituted in 1993 when the state split policy from industry.

The register's first chapter closes with the pattern stated plainly. Every founding has the same anatomy: a technical shock, a founding act, a founding doctrine, and a founding generation. The shock for most of the roster came secondhand, the orbiting beep heard in every capital at once, and the acts that followed it, within a decade, produced the agencies that still hold most of the register's mass. The reader who knows the founding acts knows the files' characters in advance, because agencies keep their doctrines for generations, and the doctrines are the subject of the chapters that follow.

One founding instrument deserves its own exhibit, the American act, because it settled a constitutional question the other files inherited the answer to: the space program is civilian. The act took the rocket out of the military's hands, assigned it to a public agency with a public charter, and required the results to be published, and the register's honest note is that the settlement was deliberate, argued, and is still contested in every generation's budget hearings. The other big files split the same question differently: the Soviet and Chinese files ran military-first and civilian-labeled, and the European settlement made the civilian consortium a treaty body above any member's forces. The register keeps the exhibit because a reader who asks why space data is mostly open will find the answer in the act's plain sentences.

The founding did not stop with the giants, and the register enters the second wave now, because the decade that opened with two spacefaring states closed with a dozen. France chartered its national office in 1961, the first of the middle-sized files, built on a national launch program the trade would eventually see folded into the European

effort. India's committee of 1962, chaired by the physicist whose doctrine the roster chapter cites, began the subcontinent's file with a rubber-riding-sounding-rocket program and a mandate to serve the common citizen. Canada organized its office around the cooperation it was already flying, Japan's founding generation ran its space science through a university institute before the modern consolidation, and Australia's early entry entered the register from the ground side, hosting the tracking stations other files needed. The wave's honest pattern, dated plainly: the second decade of the space age was founded on instruments and ranges rather than flags, and the files that began as ground stations and sounding programs are, several of them, the big files' oldest customers and steadiest partners today, which is the register's earliest evidence that the trade is built from the ground up.
