Introduction

The trade has a short list of worlds it would cross the solar system for, and most of the list is wet. This book is the atlas of the ocean worlds: the moons and planets where water, the most consequential molecule in the sky, has gathered in amounts that matter, on the surface or beneath it, in the one known example and in the dozens of strong suspects. The reader who finishes these pages will hold the trade's whole wet census, the evidence for each entry stated plainly, and the honest ledger of what is known, what is suspected, and what the instruments still cannot see.

The ledger's own weight calls for its note, the census's surprising size. A generation before the atlas's writing, the file held one ocean world and a handful of speculations, and the modern ledger holds a certain member, a well-evidenced tier of flagship seas, a candidate list numbering in the tens, and an exo-census growing by the year, the province the sky's own fastest-growing address, and the reader's first orientation the atlas's own: the subject is not the one known sea the reader learned in school, the subject is the dozens, the ledger's growth the trade's own story, entered as the book's first claim on the reader's attention, and the attention, earned.

The attention's own test takes its note, the census's growth witnessed. The file grew within the atlas's own writing span: the cueball moon promoted on a wobble, the exo-census's water worlds doubled by the transit files, the brine at the belt confirmed by the archive, and the reader's attention the file's own witness, the growth the atlas's first claim, and the claim, tested on the file's own record, the attention, earned, and the claim, held.

The subject is new enough to have a birthday the trade can name. The term ocean world entered the working vocabulary in the two thousands, when the outer-solar-system probes had made the case that several moons hold buried seas, and the field needed a word for the class before it could argue for the missions. The word did real work: it gathered Europa, Enceladus, Titan, and Ganymede under one banner and told the funding committees that these were not four exotic moons but one habitable province, the solar system's second waterfront. The atlas uses the word the way the trade uses it, as a label for any body holding a stable, globe-girdling sea, surface or buried, water in the main though the molten exception gets its page.

The exception's own lesson gets its note, the engine's overdrive entered. The molten moon is the province's cautionary tale as well as its exception: the same tidal engine that keeps the buried seas liquid ran hot at the inner address, the moon kneaded past the sea's survival into the rock's own melting, the surface the most volcanic body the trade knows, the overdrive the dial's own warning, and the lesson the engine's: the same physics that waters the province can burn its nearest address, the exception, entered, and the dial, the trade's own respect, kept.

The book's own guard, stated up front: every entry travels with the proof that earned it, instrument or arithmetic named in the file, and the sorting follows the claim's strength. The certain, Earth itself and the three buried seas whose water has been tasted. The well-evidenced, the moons whose oceans are the only clean explanation of what the probes measured. The candidates, the bodies where a single observation or a model argues for a sea and the next mission will be asked to settle the file. And the exo-census, the water worlds of other stars, read through their densities and their atmospheres, the trade's newest and hardest reading. The reader is invited to check every entry against its tier, the atlas's honesty living in the sorting.

The sorting's own guard ends with its entry, the tiers' honest maintenance. The tiers are not permanent honors: the flagship tier has held its members for decades, and the candidate tier has promoted and demoted within the atlas's own writing span, the cueball moon raised a tier on its wobble alone, the older candidate entries cooled by the better models, and the atlas's custom is to date the tier with the entry, the standing always the instrument's own, and the reader's guard the simple one: no tier is claimed without its measurement named, the sorting, maintained, and the honesty, the file's own spine, kept.

The spine's own load ends with the entry's close, the sorting's final service. The tiers let the reader hold the whole province in one hand, the certain and the argued, the scheduled and the waiting, and the sorting's service is the memory's own: the atlas's reader will forget details and keep the shape, the shape the sorting's gift, and the file's spine, carrying the whole census in the reader's own keeping, delivered, held, and used.

The book's chapters run from the ground up. The word and the trade first, then Earth as the type specimen, then the water's cosmic supply, then the physics that keeps a buried sea liquid in the outer cold, then the flagship worlds one by one, then the candidates, then the dwarf waters, then the exo-census, then the reading methods, then the habitability question, then the missions, and the ledger at the close. The reader who wants the beauty of

the subject will find it in the plumes and the cracked ice, and the reader who wants the physics will meet the beauty's own arithmetic, both readers served by the same pages, the book's whole design.

Chapter 01: The Word and the Trade

Every atlas begins with its word, and the word ocean world has a history worth an entry. The phrase circulated loosely for decades, a science-fiction coinage and a casual label, until the outer-planet trade adopted it in earnest in the two thousands. The occasion was the maturing file on the buried seas: the Galileo probe's magnetic readings at Europa, the Cassini probe's first tastes of the Enceladus plume, the accumulating case for Titan's internal water. The field had been treating these moons as separate curiosities, each with its own literature, and the phrase gave the trade what a class always gives a science: a single argument for a single province, and a single budget line for its exploration.

The definition the trade settled on is functional rather than poetic. An ocean world is a body hosting a stable, globe-girdling sea of liquid, water in the standard case, held against the cold by ice above and heat below. The words do real sorting. Stable excludes the transient, the melted-then-refrozen. Globe-girdling excludes the local lake, interesting but not an ocean. And the standard case, water, has one famous molten exception, the innermost great moon, whose sea is rock, and whose page the atlas keeps as the reminder that the word's center is liquidity, not water itself. The trade's other coinages sort beside it: the exoplanet file's water world, a planet whose bulk carries a large fraction of water by mass, and the older hydrosphere, the water envelope as a whole, surface and buried alike.

The vocabulary's own lesson closes with its note, the words as instruments. The trade's labels do the measuring the trade cannot yet do: ocean world the class, water world the bulk, hydrosphere the envelope, the words sorting the file before the instruments settle it, and the atlas's reader equipped with the words holds the arguments' own grammar, the naming the science's own first act, the vocabulary, entered, and the reader, fluent.

The word's arrival changed the trade's behavior in ways the atlas should enter. Before the label, mission proposals argued for single moons, one orbiter per target, and each was weighed alone against the other offerings of the decade. After the label, the proposals could argue for the province: an ocean worlds program, a survey of the waterfront, the individual moons as the province's towns. The trade's decadal reviews, the field's own parliament, took up the word in the twenty tens, and the flagship missions now flying or building were argued in its vocabulary. The atlas's reader should hold the history plainly: the word did not discover the oceans, the instruments did, but the word organized their exploration, and the book's subject, the class itself, is the word's monument.

The chapter's close enters the word's honest limits. The label ocean world is a hypothesis in most of its applications, not an observation: the trade has one certain member of the class and a large file of suspects, and the phrase risks running ahead of the evidence when it is used as a settled fact. The atlas's custom is to use the word for the class and the tier system for the claims, ocean world the province, certain or well-evidenced or candidate the individual member's standing, the two habits together keeping the vocabulary honest. The reader carrying both habits into the later chapters will always know what is known and what is argued, and the atlas's first lesson, delivered by the word's own history, is that the trade's best labels earn their keep by being checked against the evidence, entered, dated, and kept honest here, the custom, begun.

The custom's first test carries its example, the word's own border case. The molten moon, the innermost of Jupiter's four, is entered in some of the trade's lists and excluded from others, the sea a magma ocean in the global sense, the liquidity present and the water absent, and the atlas's ruling is the tier system's own: the moon is entered in the class's physics chapter and held out of the water census, the entry's note stating the ruling's reason, the class's center the liquid and the book's center the water, the two readings both honest, the ruling stated once and applied throughout, the custom's guard, kept.

The guard's own service keeps its note, the reader's first tool. The atlas's ocean census will not count the molten moon, and the reader meeting other books' lists that do can now audit the difference: the lists disagree at the border because the definitions differ, and the atlas's ruling is stated where the reader can check it, the border's transparency the guard's own service, the reader's first practice in the method, and the tool, delivered, the audit, the reader's own, begun.

The label's own burden collects its entry, the vocabulary's honest cost. To call a moon an ocean world is to make a claim about the interior rather than the surface, and the claim is always an inference: the shell, the mass, the wobble, the plume, each a proxy for a sea nobody has photographed, and the trade's discipline is to keep the

proxy visible in the wording, the file saying suspected, modeled, or argued where the evidence has not yet earned the plain noun. The reader should treat the vocabulary as the trade does, as a set of working verdicts rather than a finished map, and the atlas keeps the verdicts dated throughout, the word's own ledger, kept.

The atlas's own reach holds its card, the word's honest sprawl. Once the trade accepted the category, the membership arguments began at both ends: the icy moons at the large end, the dwarf's buried brine and the comets' own dirty ice at the small end, and the sprawl is the vocabulary's own honesty, the file refusing to narrow the class to the pretty examples. The reader should expect the arguments to continue, the category being a working tool rather than a museum case, and the reach, stated at both ends, the membership, argued, and the sprawl, the word's own extent, kept.
